

When working on coding projects, I have developed skills in **programming, debugging, problem-solving, and logical thinking**. I have experience writing code, finding errors, and improving my programs when they do not work as expected. I also use AI sometimes as a tool to help me understand programming concepts, identify possible errors, and learn different ways to solve a coding problem.

One of my **mistakes** is that I sometimes have difficulty finding the cause of an error, especially when my code contains multiple problems. There are also times when I make syntax mistakes or misunderstand how a particular function works. Before, I sometimes depended too much on AI when I encountered difficult coding problems. I learned that I should first try to solve the problem myself and understand the error before asking AI for assistance.

My **coding skills** include **HTML, CSS, JavaScript, Python, basic database/SQL, debugging, and problem-solving**. I am continuously improving these skills by practicing and creating small projects. When I use AI, I treat it as a learning and support tool rather than allowing it to do all of my work. I make sure that I understand the code before using it and test the code myself.

I also learned that responsible AI use is important. I avoid sharing passwords, private information, or sensitive project data with AI. I take responsibility for my own code and make sure that the final work represents my own understanding and effort.
